- Scala type classes

- A type class and its instances

- Example: type class `Printable[A]`

- Better Design

- Where to store the instances?

- Type classes without import tax

- Benefit of type classes

- Type classes in Haskell

Recap: Implicits

- Implicit declarations
  ```
  implicit val x: X = …
  implicit def func: X = …
  implicit object X extends MyTrait { … }
  ```

- Implicit parameters
  ```
  def method(implicit x: X): R = …
  ```

- Implicit conversions (a.k.a. implicit views)
  ```
  implicit def aToB(a: A): B = …
  ```

- Implicit classes
  ```
  implicit class Y(x: X) { … }
  ```

Recap: Implicit parameter resolution

- If you do not give an argument to an implicit parameter, the compiler tries to provide one for you.

- Eligible are all implicit values that are visible at the point of call.

- If there is more than one eligible candidate, the most specific one is chosen.

- If there is no unique most specific candidate, an ambiguity error is reported.

Recap: Implicit parameter resolution

- The details of implicit parameter resolution are very complex and not covered here. There are 2 main resolution steps.

- Step 1: Implicit parameters are first looked up in **"local scope"**: local declarations, imports (explicit or wildcard), inheritance (base classes or traits), local package object.

- Step 2: If implicit parameters cannot be resolved from the local scope the compiler searches the **"implicit scope"**: companion object of the implicit parameter type and the package object of their type parameters (if any).

- Local scope always takes precedence over implicit scope.

- There are other precedence rules within implicit scope (specificity, inheritance) which are not covered here.

Recap: Implicit views/conversions

- An implicit conversion is an implicit function which converts a value of type A to a value of type B.

- Use with caution: Can easily undermine type safety!!!

```scala
import scala.language.implicitConversions      // suppress warnings

implicit def string2int(s: String): Int = Integer.parseInt(s)

val x: Int = "5"                    // !! Assign a string to an int val

def useInt(x: Int): Unit = println("Int value: " + x)
useInt("42")                        // !! Pass a string to an int param
```

Recap: Implicit views

- Define an implicit class

- The class must have a single parameter of the type in question.

- Define extension methods inside the class.

- This technique is also called the "*Pimp up my library*" pattern, some times also known as "*static monkey patching*".

Pimpin' - Implicit views (1)

```scala
// Implicit view/conversion: Int => EnrichedInt
implicit class EnrichedInt(i: Int) {
  def double: Int = 2 * i
  def triple: Int = 3 * i
  def square: Int = i * i
  def cube: Int = i * i * i
}

val double5: Int = 5.double // 10
val triple5: Int = 5.triple // 15
val squared5: Int = 5.square // 25
val cubed5: Int = 5.cube // 125
val doubledSquared5 = 5.double.square // 100
```

Pimpin' - Implicit views (2)

```scala
final case class Cat(name: String, age: Int, color: String)

// Implicit view/conversion: Cat => PimpedCat
implicit class PimpedCat(c: Cat) {
  def description: String =
      s"${c.name} is a ${c.age} year old ${c.color} colored cat."
  def describe(): Unit = println(c.description)
}

val mizzi = Cat("Mizzi", 1, "black")

val desc = mizzi.description
println(desc)

mizzi.describe()
```

Pimpin' - Implicit views (3)

```scala
// Implicit view/conversion: List => PimpedList
implicit class PimpedList[A](xs: List[A]) {
  def zipWith[B, C](ys: List[B])(f: (A, B) => C): List[C] =
    xs zip ys map { case (x, y) => f(x, y) }
}

val l1 = List(1, 2, 3)
val l2 = List(10, 20, 30)

val result = l1.zipWith(l2)(_ + _)
println(result) // --> List(11, 22, 33)
```

Pimpin' - Implicit views (4)

```scala
class PimpedList[A](xs: List[A]) {
  def zipWith[B, C](ys: List[B])(f: (A, B) => C): List[C] =
    xs zip ys map { case (x, y) => f(x, y) }
}

// Implicit view/conversion: List => PimpedList
implicit def pimpList[A](xs: List[A]): PimpedList[A] =
                        new PimpedList[A](xs)

val l1 = List(1, 2, 3)
val l2 = List(10, 20, 30)

val result = l1.zipWith(l2)(_ + _)
println(result) // --> List(11, 22, 33)
```

Mechanics of implicit views

- The compiler looks up a method for a class.

- If the class implements the method, this one is used.

- If the class doesn't implement the method, it looks for an implicit conversion method or an implicit class that takes a parameter of the type in question.

- If the implicit class implements the method in question, it creates an instance, passes the parameter and invokes the method.

- Otherwise the compiler will bail out.

Type Classes

- Type classes are a fundamental concept in Scala and Haskell.

- Haskell provides specific keywords for type classes.

- Scala implements type classes based on implicits.

- A type class classifies a set of types by their common properties.

- E.g. the Scala type class `Numeric` (Haskell: `Num`) defines the arithmetic operations (as methods) which are common to all numeric types such as Int, Long, Float, Double, BigInteger, BigDecimal etc.

Examples: List methods

```scala
class List[+A] {

    // …

    def sum[B >: A](implicit num: Numeric[B]): B

    def sorted[B >: A](implicit ord: math.Ordering[B]): List[A]

    def map[B, That](f: (A) => B)
               (implicit bf: CanBuildFrom[List[A], B, That]): That

    // …

}
```

Some Type Classes (Scala)

- `scala.math.Ordering[T]`

- `scala.math.Numeric[T]`

- `scala.collection.generic.`
  `        CanBuildFrom[-From, -Elem, +To]`

- JSON Serialization (in play-json etc.)

- `cats.{Show, Monoid, Functor, Monad …}`

- There is hardly a Scala library not using type classes.

How to use the Type Class Pattern

1) Define a type class - a trait with at least one type parameter.

```
trait Printable[A] { … }
```

2) For each type to support implement a type class instance. Each instance replaces the type parameter `A` by a concrete type (`Int`, `Date`, `Cat`, `Option[A]`, etc.).

```
implicit val intPrintable Printable[Int] = …

implicit val catPrintable Printable[Cat] = …
```

3) Provide a generic user interface with an implicit type class parameter.

```
def myPrint[A](value: A)(implicit p: Printable[A]) = …
```

Define a type class (1)

```scala
// the type class,
// a trait with at least one type parameter
//
trait Printable[A] {
  def stringify(value: A): String
}
```

Define type class instances (2)

```scala
// type class instance for Int
//
implicit val intPrintable: Printable[Int] = new Printable[Int] {
  override def stringify(value: Int): String = value.toString
}

// type class instance for Date
//
implicit val datePrintable: Printable[Date] = new Printable[Date] {
    override def stringify(value: Date): String = value.toString
}

// generic type class instance for Option[A] (must be a def)
// requires an implicit Printable[A]
//
implicit def optionPrintable[A]
    (implicit pA: Printable[A]): Printable[Option[A]] = ???
```

Use the type class instance (3)

```scala
// interface function for Printable
//
def myPrint[A](value: A)(implicit p: Printable[A]): Unit =
  println(p.stringify(value))

myPrint(2)
myPrint(new Date)

myPrint(Option(2))
myPrint(Option(new Date))
```

Define type class instances (2)

```scala
final case class Cat(name: String, age: Int, color: String)

object Cat {

  implicit val catPrintable: Printable[Cat] =
                              new Printable[Cat] {
    override def stringify(cat: Cat): String = {
      val name  = Printable.stringify(cat.name)
      val age   = Printable.stringify(cat.age)
      val color = Printable.stringify(cat.color)
      s"$name is a $age year-old $color cat."
    }
  }
}
```

Generic type class instances (2)

```scala
// a generic instance for Option[A] is a def with a type
// parameter A and an implicit Printable[A]. That means:
// if you can stringify an A, you also can stringify Option[A]
//
implicit def optionPrintable[A]
        (implicit pA: Printable[A]): Printable[Option[A]] =
        new Printable[Option[A]] {

  override def stringify(optA: Option[A]): String =
    optA.map(pA.stringify)
      .map(s => s"Option($s)")
      .getOrElse("None")
}
```

Use the type class instances (3)

```scala
val mizzi = Cat("Mizzi", 1, "black")
val garfield = Cat("Garfield", 38, "ginger and black")

def myPrint[A](value: A)(implicit p: Printable[A]): Unit =
  println(p.stringify(value))

myPrint(mizzi)
myPrint(garfield)

myPrint(Option(garfield))
myPrint(Option.empty[Cat])

myPrint(List(mizzi, garfield))
myPrint(List.empty[Cat])
```

Better Design

- Move `stringify` and `pprint` methods into an object (e.g. the companion object or package object of the type class).

- With a pimp (implicit class) type class methods can be used just like intrinsic methods of the respective type.

- The implicit class constructor must have a (typically generic) parameter.

- The implicit class methods take an implicit type class parameter.

Better Design (1)

- Move the interface object methods (`stringify` and `pprint`) into a singleton object (e.g. the companion object or package object of the type class).

```scala
// type class companion object
object Printable {

  // interface object methods for the type class
  def stringify[A](value: A)(implicit p: Printable[A]): String =
      p.stringify(value)
  def pprint[A](value: A)(implicit p: Printable[A]): Unit =
      println(stringify(value))
}
- - - - -
package userpkg

import path.to.libPrintable._

Printable.pprint(mizzi)
```

Better Design (2)

- Use a pimp by defining a generic implicit class. (The constructor has one parameter of the generic type. Methods take a type class instance as implicit parameter.)

```scala
// interface syntax methods defined by a pimp (= implicit view)
//
implicit class PrintableOps[A](value: A) {
  def stringify(implicit p: Printable[A]): String = p.stringify(value)
  def pprint(implicit p: Printable[A]): Unit = println(stringify)
}

val stringMizzi = mizzi.stringify
println(stringMizzi)

mizzi.pprint
```

Where to keep type class instances?

- Type class instances for standard types (`String`, `Int`, `Date` etc.) should be stored under the same package as the type class itself (typically in companion object of the type class).

- Type class instances for your own types, i.e. domain classes (`Cat`, `Person`, `Customer`, `Order`, `Invoice` etc.) should be stored under the same package as the respective domain class (typically in the companion object of the domain class).

Only one import

- The library should provide the type class instances in a **non-intrusive** way so that user code easily can override them.

- User code needs only **one import statement**:
  ```
  import path.to.libPrintable._
  ```

- Type class instances in the type class companian object are found automatically without extra import. They are visible in the **implicit scope** (which can be overridden by local scope):

- Interface object methods and implicit class can be moved to the library's package object. By the above import they become visible in **local scope**. (Can be improved, see below.)

- If needed the user can provide his own instances in local scope: local declaration, import (explicit or wildcard), inheritance (base class or trait), package object.

- Local scope precedes implicit scope.

Only one import - code

```scala
package path.to.libPrintable

object Printable {
  implicit val intPrintable: Printable[Int] = ???
  implicit val datePrintable: Printable[Date] = ???
  implicit def optionPrintable[A: Printable]: Printable[Option[A]] = ???
}

- - - - -

package path.to

package object libPrintable {

  def stringify[A](value: A)(implicit p: Printable[A]): String = p.stringify(value)
  def pprint(value: A)(implicit p: Printable[A]): Unit = println(stringify(value))

  implicit class PrintableOps[A](value: A) {
    def stringify(implicit p: Printable[A]): String = p.stringify(value)
    def pprint(implicit p: Printable[A]): Unit = println(stringify)
  }
}

- - - - -

package userpkg

import path.to.libPrintable._ // only one import needed

2.pprint
new Date().pprint
mizzi.pprint
```

Context Bound + implicitly (1)

```scala
// implicit class (without context bound)
//
implicit class PrintableOps[A](value: A) {
  def stringify(implicit p: Printable[A]): String = p.stringify(value)
  def pprint(implicit p: Printable[A]): Unit = println(stringify)
}

- - - - -

// implicit class (with context bound and implicitly)
//
implicit class PrintableOps[A: Printable](value: A) {
  def stringify: String = implicitly[Printable[A]].stringify(value)
  def pprint(): Unit = println(stringify)
}
```

Context Bound + implicitly (2)

```scala
// interface object methods (without context bound)
//
def stringify[A](value: A)(implicit p: Printable[A]): String =
    p.stringify(value)
def pprint[A](value: A)(implicit p: Printable[A]): Unit =
    println(stringify(value))

- - - - -

// interface object methods (with context bound and implicitly)
//
def stringify[A: Printable](value: A): String =
    implicitly[Printable[A]].stringify(value)
def pprint[A: Printable](value: A): Unit =
    println(stringify(value))
```

Method apply

```scala
object Printable {

  def apply[A: Printable]: Printable[A] =
    implicitly[Printable[A]]

  def stringify[A: Printable](value: A): String =
    Printable[A].stringify(value)

  ...
}
```

No more imports

- Move interface object methods and the pimp into a trait (e.g. `PrintableUtils`).

- The local package object (user code) extends that trait and brings them into local scope.
  ```
  package object userpkg extends PrintableUtils
  ```

- Interface object methods and pimp can easily be overridden in the local package object.

- This architecture is **least intrusive** and gives good flexibility to the library user.

- **No library imports** needed

No more imports - code

```scala
package path.to.libPrintable

object Printable {
  implicit val intPrintable: Printable[Int] = ???
  implicit val datePrintable: Printable[Date] = ???
  implicit def optionPrintable[A: Printable]: Printable[Option[A]] = ???
}

trait PrintableUtils {
  def stringify[A](value: A)(implicit p: Printable[A]): String = p.stringify(value)
  def pprint(value: A)(implicit p: Printable[A]): Unit = println(stringify(value))

  implicit class PrintableOps[A](value: A) {
    def stringify(implicit p: Printable[A]): String = p.stringify(value)
    def pprint(implicit p: Printable[A]): Unit = println(stringify)
  }
}
– – – – –
package userpkg

import path.to.libPrintable.{Printable, PrintableUtils}

package object userpkg extends PrintableUtils {
  // In the users package object base trait utilities and implicits can be overridden.

  override def pprint[A: Printable](value: A): Unit = ???         // overrides default impl

  implicit class MyPrintableOps[A: Printable](value: A) extends PrintableOps(value) {
    override def pprint(implicit p: Printable[A]): Unit = ???     // overrides default impl
  }
}
```

Type class cats.Show

- If you are using cats ...

- No need to implement the Printable type class

- Cats already provides such a type class:
  `cats.Show`

Type classes in Cats

- Cats provides most of its functionality as type classes: `cats.{Show, Eq, Ord, Num, Monoid, Functor, Monad, Applicative, Foldable}` and many more.

- See https://typelevel.org/cats/typeclasses.html

Benefit of type classes

- Separation of abstractions: The type class (`Printable`) and the type you create an instance for, e.g. a domain class (`Cat`) are completely decoupled.

- Extensibility: You can extend and enrich not only your own types but also sealed types from libraries which you do not control.

- Composability: You do not need inheritence to extend existing classes or library classes (which is not possible if they are sealed).

- Overridability (only Scala): Default instances (in companion object) can be overridden with your own instances.

- Less repetition and boilerplate, e.g. avoids repetitive passing of parameters and overloads.

- Type safety is maintained.

Downsides of type classes

- Type classes and implicits are hard to understand for the Scala newcomer (complicated rules of implicit resolution).

- Overuse of implicits often makes Scala code too difficult to read/understand.

- Implicits (and some other features) give Scala the reputation to be an arcane language.

- Resolution of implicit parameters and conversions may slow down the compiler.

Type classes in Haskell

- Define a type class.

  ```
  class Printable a where …
  ```

- Create an instance for each type that should support the type class. (This enriches each type with the methods of the type class.)

  ```
  instance Printable Int where …
  instance Printable Cat where …
  ```

- That's it. Just use the type class methods for the types that have an instance. No extra user interface needs to be provided (like in Scala).

Define a type class

```haskell
class Printable a where

    -- stringify: signature
    stringify :: a -> String

    -- pprint: signature + impl
    pprint :: a -> IO ()
    pprint x = putStrLn $ stringify x
```

Define type class instances (1)

```haskell
instance Printable Int where

    stringify = show

instance Printable UTCTime where

    stringify time = "The exact date is: "
            ++ formatTime defaultTimeLocale "%F, %T (%Z)" time
```

Define type class instances (2)

```haskell
data Cat = Cat
  { name  :: String
  , age   :: Int
  , color :: String
  }

instance Printable Cat where
    stringify cat = "Cat { name=" ++ name cat
                            ++ ", age=" ++ show (age cat)
                            ++ ", color=" ++ color cat ++ "}"
```

Use the type class methods with the instance types.

```
putStrLn $ stringify $ utcTime 2018 4 9 19 15 00

pprint $ utcTime 2018 4 9 19 15 01

let mizzi = Cat "Mizzi" 1 "black"

putStrLn $ stringify mizzi

pprint mizzi
```

Type class Show

- No need to implement the `Printable` type class
- Haskell already has a type class `Show` in the Prelude

Type classes in Haskell

- Many type classes are available in the Haskell Prelude, i.e. without extra import.

- Haskell provides its own kosmos of type classes in Base (the standard library), most of them available in the Prelude: `Show`, `Eq`, `Ord`, `Num`, `Integral`, `Fractional`, `Monoid`, `Functor`, `Applicative`, `Monad`, `Foldable` etc.

Comparison

- Haskell has its own type class syntax (key words `class` and `instance`).

- Scala uses implicits to provide type classes.

- In Scala (using implicit val ...) you need to create an object for each type class instance.

- No object creation in Haskell.

- No implicit hocus-pocus in Haskell.

- No objects, no inheritance in Haskell

- Haskell type classes are coherent. Haskell allows globally only one type class instance per type. => No ambiguity errors! No precedence rules needed!
